PRELIMINARIES

1.1 JUST ENOUGH CATEGORY THEORY TO BE DANGEROUS

1.1.1 AN INTRODUCTION TO ABELIAN CATEGORIES

Definition 1.1.1 (additive category, additive functor)

A category \mathcal{C} is said to be additive if it satisfies the following properties

1. for each $A, B \in \mathcal{C}$, $\text{Hom}(A, B)$ is an abelian group and composition distributes over addition of morphisms

$$f \circ (g + h) = f \circ g + f \circ h$$

$$(g + h) \circ f = g \circ f + h \circ f$$

for every morphisms f, g, h in \mathcal{C}

2. \mathcal{C} has a zero object
3. \mathcal{C} has biproduct of finitely many objects

A functor $F : \mathcal{C} \rightarrow \mathcal{D}$ from an additive category \mathcal{C} to another additive category \mathcal{D} is called additive if it preserves additive structure

$$F(f \circ g) = F(f) \circ F(g)$$

$$F(f + g) = F(f) + F(g)$$

Definition 1.1.2 (kernel, cokernel, image, coimage)

Let $f : A \rightarrow B$ be a morphism in a category \mathcal{C} with a zero object

1. a kernel for f is an object $K \in \mathcal{C}$ together with a universal map $i : K \rightarrow A$ so that $f \circ i = 0$
2. a cokernel for f is an object $Q \in \mathcal{C}$ together with a universal map $p : B \rightarrow Q$ so that $p \circ f = 0$. the object of cokernel of $f : A \rightarrow B$ is also written as A/B

3. image/coimage for f are defined by

$$\text{im } f = \text{ker coker } f, \text{ coim } f = \text{coker ker } f$$

Definition 1.1.3 (abelian category)

An abelian category is an additive category satisfying additional properties

1. every map has a kernel and a cokernel
2. every monomorphism is the kernel of its cokernel
3. every epimorphism is the cokernel of its kernel

Theorem 1.1.4 (Frey-Mitchell Embedding Theorem)

If \mathcal{C} is an abelian category whose objects form a set, then there is a ring A and an exact, fully faithful functor $\mathcal{C} \rightarrow \text{Mod}_A$ which embeds \mathcal{C} as a full subcategory (A is not necessary commutative)

By Frey-Mitchell Embedding Theorem, to prove something about diagram in some abelian category, we may assume that it is a diagram of modules over ring and use diagram chasing techniques

Definition 1.1.5 (complex, exactness, homology)

Given a sequence of morphisms in an abelian category

$$\dots \rightarrow A \xrightarrow{f} B \xrightarrow{g} C \rightarrow \dots$$

The sequence is said to be a complex at B if $g \circ f = 0$, the sequence is said to be exact at B if $\ker g = \text{im } f$. Note that, being exact at B implies being complex at B . If the sequence is complex/exact everywhere, then it is called complex/exact. if the sequence is complex at B , then its homology at B is defined by $\ker g / \text{im } f$

Proof. $\ker g / \text{im } f$ is well-defined by the following:

The composition $A \rightarrow B \rightarrow \text{coker } f$ is zero, $\text{im } f$ is the kernel of $B \rightarrow \text{coker } f$, hence $f : A \rightarrow B$ factors through $\text{im } f$ by a unique map $A \rightarrow \text{im } f$

The composition $A \rightarrow B \rightarrow C$ is zero, $\text{coker } f$ is the kernel of $f : A \rightarrow B$, hence $g : B \rightarrow C$ factors through $\text{coker } f$ by a unique map $\text{coker } f \rightarrow C$

The composition $\text{im } f \rightarrow B \rightarrow \text{coker } f \rightarrow C$ is zero, hence the composition $\text{im } f \rightarrow B \rightarrow C$ is zero, $\ker g$ is the kernel of $g : B \rightarrow C$, hence, $\text{im } f \rightarrow B$ factors through $\ker g$ by a unique map $\text{im } f \rightarrow \ker g$

Homology at B is defined by the cokernel of the map $\text{im } f \rightarrow \ker g$

□

Proposition 1.1.6 (factoring a long exact sequence into short exact sequences)

Given a long exact sequence A^\bullet

$$\dots \rightarrow A^{i-1} \xrightarrow{f^{i-1}} A^i \xrightarrow{f^i} A^{i+1} \rightarrow \dots$$

Then it can be factored into short exact sequences

$$0 \rightarrow \ker f^i \rightarrow A^i \rightarrow \ker f^{i+1} \rightarrow 0$$

More generally, if A^\bullet is only a complex then it can be factored into

$$0 \longrightarrow \ker f^i \longrightarrow A^i \longrightarrow \operatorname{im} f^i \longrightarrow 0$$

$$0 \longrightarrow \operatorname{im} f^{i-1} \longrightarrow \ker f^i \longrightarrow H^i(A^\bullet) \longrightarrow 0$$

$$0 \longrightarrow \operatorname{im} f^i \longrightarrow A^{i+1} \longrightarrow \operatorname{coker} f^i \longrightarrow 0$$

$$0 \longrightarrow H^i(A^\bullet) \longrightarrow \operatorname{coker} f^{i-1} \longrightarrow \operatorname{im} f^i \longrightarrow 0$$

Definition 1.1.7 (category of complexes)

Suppose \mathcal{C} is an abelian category, then the category of complexes in \mathcal{C} consists of objects being infinite complexes in \mathcal{C} and morphisms $A^\bullet \rightarrow B^\bullet$ being commutative diagrams

$$\begin{array}{ccccccc} \dots & \longrightarrow & A^{i-1} & \longrightarrow & A^i & \longrightarrow & A^{i+1} \longrightarrow \dots \\ & & \downarrow & & \downarrow & & \downarrow \\ \dots & \longrightarrow & B^{i-1} & \longrightarrow & B^i & \longrightarrow & B^{i+1} \longrightarrow \dots \end{array}$$

The object and morphism are also called chain complex and chain map. The category of complexes in \mathcal{C} is an abelian category.

Proposition 1.1.8 (chain map induces a map in homology)

A chain map $f : A^\bullet \rightarrow B^\bullet$ induces maps in homology $f^* : H^i(A^\bullet) \rightarrow H^i(B^\bullet)$

$$\begin{array}{ccccc} \ker f^i & \longrightarrow & A^i & \xrightarrow{f^i} & A^{i+1} \\ \downarrow & & \downarrow & & \downarrow \\ \ker g^i & \longrightarrow & B^i & \xrightarrow{g^i} & B^{i+1} \end{array}$$

Definition 1.1.9 (homotopic, homotopy, homotopy equivalence)

Two chain maps $f : A^\bullet \rightarrow B^\bullet$ and $g : A^\bullet \rightarrow B^\bullet$ are called homotopic if there exists a homotopy h from f into g , that is a sequence of maps $h : A^i \rightarrow B^{i-1}$ so that $f - g = dh + hd$

$$\begin{array}{ccccccc}
 \dots & \longrightarrow & A^{i-1} & \xrightarrow{d} & A^i & \xrightarrow{d} & A^{i+1} & \longleftarrow & \dots \\
 & \searrow & & \swarrow h & & \swarrow h & & \searrow & \\
 \dots & \longrightarrow & B^{i-1} & \xrightarrow{d} & B^i & \xrightarrow{d} & B^{i+1} & \longrightarrow & \dots
 \end{array}$$

Being homotopic is an equivalence relation. If f and g are homotopic, we write $f \sim g$.

If there is another chain map $f' : B^\bullet \rightarrow A^\bullet$ so that $f \circ f' \sim 1_{B^\bullet}$ and $f' \circ f \sim 1_{A^\bullet}$, then A^\bullet and B^\bullet are called homotopy equivalence which is also an equivalence relation.

Proposition 1.1.10 (homotopic maps induce the same map in homology)

If $f \sim g$ where $f : A^\bullet \rightarrow B^\bullet$ and $g : A^\bullet \rightarrow B^\bullet$ are two chain maps, then $f^* = g^*$ where $f^* : H^i(A^\bullet) \rightarrow H^i(B^\bullet)$ and $g^* : H^i(A^\bullet) \rightarrow H^i(B^\bullet)$ are the induced maps in homology

Theorem 1.1.11 (short exact sequence of chain complexes induces a long exact sequence in homology)

A short exact sequence of chain complexes

$$0 \rightarrow A^\bullet \rightarrow B^\bullet \rightarrow C^\bullet \rightarrow 0$$

induces a long exact sequence in homology

$$\begin{array}{ccccccc}
 H^{i+1}(A^\bullet) & \longrightarrow & \dots & & & & \\
 & \swarrow & & \searrow & & & \\
 H^i(A^\bullet) & \longrightarrow & H^i(B^\bullet) & \longrightarrow & H^i(C^\bullet) & & \\
 & \swarrow & & \searrow & & & \\
 & & \dots & \longrightarrow & H^{i-1}(C^\bullet) & &
 \end{array}$$

Definition 1.1.12 (exactness of functors)

Exactness of functor is characterized as follows:

1. If $F : \mathcal{A} \rightarrow \mathcal{B}$ is an additive covariant functor from abelian category to abelian category then

- (a) F is right-exact if the top sequence being exact implies the bottom sequence being exact

$$A_1 \longrightarrow A_2 \longrightarrow A_3 \longrightarrow 0$$

$$F(A_1) \longrightarrow F(A_2) \longrightarrow F(A_3) \longrightarrow 0$$

- (b) F is left-exact if the top sequence being exact implies the bottom sequence being exact

$$0 \longrightarrow A_1 \longrightarrow A_2 \longrightarrow A_3$$

$$0 \longrightarrow F(A_1) \longrightarrow F(A_2) \longrightarrow F(A_3)$$

2. If $F : \mathcal{A} \rightarrow \mathcal{B}$ is an additive contravariant functor from abelian category into abelian category, then

- (a) F is right-exact if the top sequence being exact implies the bottom sequence being exact

$$0 \longrightarrow A_1 \longrightarrow A_2 \longrightarrow A_3$$

$$F(A_3) \longrightarrow F(A_2) \longrightarrow F(A_1) \longrightarrow 0$$

- (b) F is left-exact if the top sequence being exact implies the bottom sequence being exact

$$A_1 \longrightarrow A_2 \longrightarrow A_3 \longrightarrow 0$$

$$0 \longrightarrow F(A_3) \longrightarrow F(A_2) \longrightarrow F(A_1)$$

A functor is exact if it is both left-exact and right-exact

Proposition 1.1.13

additive functor preserves chain complex, exact functor preserves exact sequence

Remark 1.1.14

If A is a ring, $S \subseteq A$ is a multiplicative subset, and M is an A -module, then

1. Localization $(S^{-1}-)$ is an exact covariant functor $\text{Mod}_A \rightarrow \text{Mod}_{S^{-1}A}$
2. Tensor product $(- \otimes_A M)$ is a right-exact covariant functor $\text{Mod}_A \rightarrow \text{Mod}_A$
3. $\text{Hom}(M, -)$ is a left-exact covariant functor $\text{Mod}_A \rightarrow \text{Mod}_A$
4. $\text{Hom}(-, M)$ is a left-exact contravariant functor $\text{Mod}_A \rightarrow \text{Mod}_A$

Theorem 1.1.15 (FernaHnHoF theorem, FHHF theorem)

Suppose $F : \mathcal{A} \rightarrow \mathcal{B}$ is a covariant functor from abelian category into abelian category and C^\bullet is a chain complex in \mathcal{A} , then

1. If F is right-exact then there is a natural map

$$FH^\bullet \rightarrow H^\bullet F$$

that is, for each i , there is a natural map $F(H^i(C^\bullet)) \rightarrow H^i(F(C^\bullet))$

2. If F is left-exact then there is a natural map

$$FH^\bullet \leftarrow H^\bullet F$$

that is, for each i , there is a natural map $F(H^i(C^\bullet)) \leftarrow H^i(F(C^\bullet))$

3. If F is exact then there is a natural isomorphism

$$FH^\bullet \xrightarrow{\sim} H^\bullet F$$

that is, exact functor preserves homology

Remark 1.1.16 (interaction of adjoint, limit, colimit, left-exact, right-exact)

interaction of adjoint, limit, colimit, left-exact, right-exact

1. limit commutes with limit and right adjoint functor. In particular, in abelian category, kernel is limit, hence both limit and right adjoint functor are left-exact
2. colimit commutes with colimit and left adjoint functor. In particular, in abelian category, cokernel is colimit, hence both colimit and left adjoint functor are right-exact

TODO - add some derived functor

1.2 SHEAVES

1.2.1 MOTIVATING EXAMPLE: THE SHEAF OF SMOOTH FUNCTIONS

TODO

1.2.2 DEFINITION OF SHEAVES AND PRESHEAVES

Definition 1.2.1 (presheaf, section)

A presheaf of sets \mathcal{F} on a topological space X is the following data:

1. for each open $U \subseteq X$, there is a set $\mathcal{F}(U)$, the elements of $\mathcal{F}(U)$ are called sections of \mathcal{F} over U
2. for each open set inclusion $U \hookrightarrow V$, there is a restriction map

$$\begin{aligned} \text{res}_{V,U} : \mathcal{F}(V) &\rightarrow \mathcal{F}(U) \\ f &\mapsto f|_U \end{aligned}$$

The data is required to satisfy the following:

1. for each open set $U \subseteq X$, the restriction map $\text{res}_{U,U}$ is identity $\text{res}_{U,U} = \text{id}_{\mathcal{F}(U)}$
2. if $U \hookrightarrow V \hookrightarrow W$ are inclusions of open sets, then the diagram below commutes

$$\begin{array}{ccccc} \mathcal{F}(W) & \xrightarrow{\text{res}} & \mathcal{F}(V) & \xrightarrow{\text{res}} & \mathcal{F}(U) \\ & \searrow & & \nearrow & \\ & & \text{res} & & \end{array}$$

In other words, presheaf is a functor from the category of open sets on X with restriction maps into the category of sets Set

Definition 1.2.2 (germ, stalk)

For any $p \in X$, consider the collection of sections of \mathcal{F} over all open sets containing p

$$\{(f, U) : p \subseteq U, f \in \mathcal{F}(U)\}$$

together with an equivalence relation \sim as follows: $(f, U) \sim (g, V)$ if and only if there exists $W \subseteq U \cap V$ containing p and $f|_W = g|_W$. The equivalence class of $f \in \mathcal{F}(U)$ is called the germ of f at p . The collection of all germs at p is called stalk of \mathcal{F} at p and denoted by \mathcal{F}_p

Remark 1.2.3 (filtered colimit, an equivalent definition of stalk)

(The Stacks project - 4.19 Filtered colimit) A diagram $M : \mathcal{I} \rightarrow \mathcal{C}$ is called directed (or filtered) if the following conditions hold:

1. the category \mathcal{I} has at least one object
2. for every pair of objects x, y of \mathcal{I} , there exists an object z and morphisms $x \rightarrow z$ and $y \rightarrow z$
3. for every pair of morphisms $a, b : x \rightarrow y$ of \mathcal{I} , there exists a morphism $c : y \rightarrow z$ so that $M(c \circ a) = M(c \circ b)$ as morphisms in \mathcal{C}

after some gibberish - the colimit of M (filtered colimit) always exists. In particular, when \mathcal{C} is \mathbf{Set} , then

$$\operatorname{colim}_{\mathcal{I}} M = \left(\coprod_{i \in \mathcal{I}} M_i \right) / \sim$$

where $m_i \sim m_j$ if and only if there exists $k \in \mathcal{I}$, $\phi_{ik} : i \rightarrow k$, $\phi_{jk} : j \rightarrow k$, and $M(\phi_{ik})(m_i) = M(\phi_{jk})(m_j)$. In formally, two elements are equal if they eventually become equal. When \mathcal{I} is the category of open sets on X with restriction maps containing p and M is \mathcal{F} , then stalk of \mathcal{F} at p is precisely the colimit of the corresponding diagram.

Remark 1.2.4

For any category \mathcal{C} , presheaf of \mathcal{C} on X is also defined similarly

Definition 1.2.5 (sheaf)

A presheaf is called a sheaf if it satisfies two additional axioms: for any open set U with open cover $\{U_i\}_{i \in I}$

1. (identity axiom) if two sections $f, g \in \mathcal{F}(U)$ have $f|_{U_i} = g|_{U_i}$ for every $i \in I$, then $f = g$
2. (gluability axiom) if for each $i \in I$, there is a section $f_i \in \mathcal{F}(U_i)$ so that for every intersection $U = U_i \cap U_j$, $f_i|_U = f_j|_U$, then there exists a section $f \in \mathcal{F}(U)$ so that $f|_{U_i} = f_i$ for every $i \in I$

Remark 1.2.6

Some remarks on sheaf

1. Informally, identity axiom says there is at most one way to glue and gluability axiom says there is at least one way to glue.
2. From the two axioms for sheaf, one can show that $\mathcal{F}(\emptyset)$ must be the final object in the target category. There is also a version of presheaf and sheaf where the empty set \emptyset is not included.
3. germ and stalk on sheaf is germ and stalk on presheaf
4. The axioms of sheaf is equivalent to say $\mathcal{F}(\bigcup_{i \in I} U_i)$ is the limit of the diagram consists of $\{\mathcal{F}(U_i)\}_{i \in I}$, all finite intersections of them, and restriction maps

**Definition 1.2.7** (restriction of sheaf)

Suppose \mathcal{F} is a sheaf on topological X and $U \subseteq X$ is an open set, then the collection of $\{\mathcal{F}(V) : V \subseteq U\}$ forms a sheaf on the subspace U of topological space X

Remark 1.2.8 (skyscraper sheaf)

Let X be a topological space, $p \in X$, and a set S . Let $i_p : p \hookrightarrow X$ be the inclusion, then define $i_{p,*}S$ by

$$(i_{p,*}S)(U) = \begin{cases} S & \text{if } p \in U \\ \{\bullet\} & \text{if } p \notin U \end{cases}$$

together with evident restriction maps, they form a sheaf and called skyscraper sheaf supported at p

Remark 1.2.9 (constant presheaf, locally constant sheaf)

Let X be a topological space and S be any set, then $\underline{S}_{pre}(U) = S$ for all $U \subseteq X$ together with evident restriction maps, they form a presheaf and called constant presheaf.

Let X be a topological space and S be any set, let $\mathcal{F}(U)$ be the set of maps $U \rightarrow S$ that are locally constant, i.e. for any $p \in U$, there is an open neighbourhood of p where the function is constant, then together with evident restriction maps, they form a sheaf and called (locally) constant sheaf and denoted by \underline{S}

Definition 1.2.10 (pushforward sheaf)

Let $\pi : X \rightarrow Y$ be a continuous map and \mathcal{F} be a presheaf on X . Define the presheaf $\pi_*\mathcal{F}$ on Y by

$$(\pi_*\mathcal{F})(V) = \mathcal{F}(\pi^{-1}V)$$

for every open set $V \subseteq Y$. Then, $\pi_*\mathcal{F}$ is a presheaf on Y and called pushforward of \mathcal{F} . If \mathcal{F} is a sheaf on X then $\pi_*\mathcal{F}$ is a sheaf on Y .

Proposition 1.2.11 (pushforward induces maps of stalks)

Let $\pi : X \rightarrow Y$ be a continuous map and \mathcal{F} be a presheaf on X . Let \mathcal{G} be the pushforward of \mathcal{F} on Y . If $p \in X$ and $q = \pi(p)$, then there is a natural map of stalks $\mathcal{G}_q \rightarrow \mathcal{F}_p$ induced from the map of representatives

Definition 1.2.12 (ringed space, \mathcal{O}_X -module)

Let \mathcal{O}_X be a sheaf of rings on topological space X , then (X, \mathcal{O}_X) is called a ringed space. \mathcal{O}_X is called the structure sheaf of the ringed space. Sections of the structure sheaf \mathcal{O}_X over an open set $U \subseteq X$ are called functions on U . A sheaf \mathcal{F} of abelian groups on ring spaced (X, \mathcal{O}_X) is called sheaf of \mathcal{O}_X -modules if each $\mathcal{F}(U)$ is an $\mathcal{O}_X(U)$ -module and the structure compatible with restriction maps, that is, for every restriction of open sets $U \rightarrow V$, the diagram below commutes

$$\begin{array}{ccc} \mathcal{O}_X(U) \times \mathcal{F}(U) & \xrightarrow{\times} & \mathcal{F}(U) \\ (\text{res}, \text{res}) \downarrow & & \downarrow \text{res} \\ \mathcal{O}_X(V) \times \mathcal{F}(V) & \xrightarrow{\times} & \mathcal{F}(V) \end{array}$$

Remark 1.2.13 (\mathbb{Z} -modules and $\underline{\mathbb{Z}}$ -modules)

a sheaf of $\underline{\mathbb{Z}}$ -modules is precisely a sheaf of abelian groups where $\underline{\mathbb{Z}}$ denotes the locally constant sheaf to \mathbb{Z} .

Remark 1.2.14 (vector bundle)

a vector bundle is precisely a locally free sheaf of \mathcal{E} -modules where \mathcal{E} is the sheaf of functions on the base space.

1.2.3 MORPHISMS OF PRESHEAVES AND SHEAVES

Definition 1.2.15 (morphism of presheaves, morphism of sheaves)

A morphism $\phi : \mathcal{F} \rightarrow \mathcal{G}$ of presheaves of sets on X is the data of maps $\phi(U) : \mathcal{F}(U) \rightarrow \mathcal{G}(U)$ for every open set $U \subseteq X$ and compatible with restriction maps, that is, for every restriction of open sets $U \rightarrow V$, the diagram below commutes

$$\begin{array}{ccc} \mathcal{F}(U) & \xrightarrow{\phi(U)} & \mathcal{G}(U) \\ \downarrow \text{res} & & \downarrow \text{res} \\ \mathcal{F}(V) & \xrightarrow{\phi(V)} & \mathcal{G}(V) \end{array}$$

A morphism of sheaves of sets is a morphism of the underlying presheaves. Morphisms of (pre)sheaves make (pre)sheaves a category and called category of (pre)sheaves.

Let Set_X , Ab_X , etc denote the categories of sheaves of sets, abelian groups, etc.

Proposition 1.2.16 (morphisms of (pre)sheaves induce morphisms of stalks)

If $\phi : \mathcal{F} \rightarrow \mathcal{G}$ is a morphism of presheaves on X . If $p \in X$, then there is a natural map $\phi_p : \mathcal{F}_p \rightarrow \mathcal{G}_p$ induced from the map of representatives. On other words, there is a functor $\text{Set}_X \rightarrow \text{Set}$ and called stalkification functor.

Proposition 1.2.17

Suppose $\pi : X \rightarrow Y$ is a continuous map of topological spaces, the pushforward gives a functor $\pi_* : \text{Set}_X \rightarrow \text{Set}_Y$

Definition 1.2.18 (sheaf Hom)

Suppose \mathcal{F} and \mathcal{G} are two sheaves of sets on X , let $\text{Hom}(\mathcal{F}, \mathcal{G})$ ^a be defined as follows: for every open set $U \subseteq X$, let

$$\text{Hom}(\mathcal{F}, \mathcal{G})(U) := \text{Hom}(\mathcal{F}|_U, \mathcal{G}|_U)$$

be the collection of morphisms of the restriction sheaves $\mathcal{F}|_U, \mathcal{G}|_U$. It is a sheaf and called "sheaf Hom"

^a*TODO - figure out how to write notation Hom correctly*

presheaves of abelian groups form an abelian category - kernel and cokernel in category of presheaves**Definition 1.2.19** (presheaf kernel, cokernel)

If $\phi : \mathcal{F} \rightarrow \mathcal{G}$ is a morphism of presheaves. Define the presheaf kernel $\ker_{\text{pre}} \phi$ and the presheaf cokernel $\text{coker}_{\text{pre}} \phi$ by

$$\begin{aligned} (\ker_{\text{pre}} \phi)(U) &= \ker \phi(U) \\ (\text{coker}_{\text{pre}} \phi)(U) &= \text{coker} \phi(U) \end{aligned}$$

for every open set U . Presheaf kernel and presheaf cokernel are presheaves and kernel and cokernel in the category of presheaves.

Remark 1.2.20

presheaves of abelian groups form an abelian category and work "open set by open set". subpresheaf, image presheaf, quotient presheaf are then defined "open set by open set"

Proposition 1.2.21

Given a topological space X , if U is an open set on X , then $\mathcal{F} \mapsto \mathcal{F}(U)$ defines an exact functor from presheaves of abelian groups into abelian groups.

Proposition 1.2.22

A sequence of presheaves $0 \rightarrow \mathcal{F}_1 \rightarrow \mathcal{F}_2 \rightarrow \dots \rightarrow \mathcal{F}_n \rightarrow 0$ is exact if and only if $0 \rightarrow \mathcal{F}_1(U) \rightarrow \mathcal{F}_2(U) \rightarrow \dots \rightarrow \mathcal{F}_n(U) \rightarrow 0$ is exact for every open set U .

problem with sheaves**Proposition 1.2.23**

If $\phi : \mathcal{F} \rightarrow \mathcal{G}$ is a morphism of sheaves, then the presheaf kernel $\ker_{pre} \phi$ is a sheaf and the kernel in the category of sheaves.

Remark 1.2.24 (presheaf cokernel is *not cokernel* in the category of sheaves)

Let $\Omega \subseteq \mathbb{C}$ be an open set, a holomorphic function $f : \Omega \rightarrow \mathbb{C}$ is called admitting holomorphic logarithm if there exists a holomorphic function $g : \Omega \rightarrow \mathbb{C}$ so that $\exp g = f$.

Let $X = \mathbb{C}$ with the usual topology, let \mathcal{O}_X be the sheaf of holomorphism functions and \mathcal{F} be the presheaf of functions admitting a holomorphic logarithm, then there is an exact sequence of presheaves on X

$$0 \rightarrow \underline{\mathbb{Z}} \rightarrow \mathcal{O}_X \rightarrow \mathcal{F} \rightarrow 0$$

where $\underline{\mathbb{Z}}$ is the constant sheaf (to \mathbb{Z}) on X , for each open set $U \subseteq X$, $\underline{\mathbb{Z}}(U) = \mathbb{Z}$. $\underline{\mathbb{Z}} \rightarrow \mathcal{O}_X$ is the natural inclusion, and $\mathcal{O}_X \rightarrow \mathcal{F}$ is given by $f \mapsto \exp(2\pi i f)$.

Then, \mathcal{F} is not a sheaf. In other words, there is a holomorphic function that locally has holomorphic logarithm but does not have global logarithm

Proof. Let $A = \{z \in \mathbb{C} : 10 < |z| < 11\} \cap \{(x, y) \in \mathbb{C} : -1 < y\}$ and $B = \{z \in \mathbb{C} : 10 < |z| < 11\} \cap \{(x, y) \in \mathbb{C} : y < +1\}$, then the identity function $z \mapsto z$ has logarithm on A and B but not on $A \cup B$ □

1.2.4 PROPERTIES DETERMINED AT THE LEVEL OF STALKS AND SHEAFIFICATION

properties determined at the level of stalks

Proposition 1.2.25 (section is determined by germs)

Given a sheaf of sets \mathcal{F} on X and any open set $U \subseteq X$, there exists an injective natural map

$$\mathcal{F}(U) \hookrightarrow \prod_{p \in U} \mathcal{F}_p$$

Proof. Let $U \subseteq X$ be an open set. For every $p \in U$, since \mathcal{F}_p is the colimit of the diagram containing $\mathcal{F}(V)$ for all V containing p , hence there is a map $\mathcal{F}(U) \rightarrow \mathcal{F}_p$. Therefore, there is a map $\mathcal{F}(U) \rightarrow \prod_{p \in U} \mathcal{F}_p$. We will show that this map is injective. Suppose two distinct functions $f, g \in \mathcal{F}(U)$, $f \neq g$ in $\mathcal{F}(U)$ but $f = g$ in $\prod_{p \in U} \mathcal{F}_p$. Then, $f = g$ in \mathcal{F}_p for every $p \in U$. For each $p \in U$, since $f = g$ in \mathcal{F}_p , there exists an open set $V_p \subseteq U$ containing p so that $f = g$ in $\mathcal{F}(V_p)$. By identity axiom, $\bigcup_{p \in U} V_p = U$ and $f = g$ in $\mathcal{F}(V_p)$ for every p , then $f = g$ in $\mathcal{F}(U)$. Contradiction. \square

Remark 1.2.26

this proposition gives the feeling that sheaf is just a "sheaf" of "stalks" stick together

Definition 1.2.27 (compatible germs)

An element $(s_p)_{p \in U} \in \prod_{p \in U} \mathcal{F}_p$ is called compatible germs if for each $p \in U$, there exists an open set $U_p \subseteq U$ containing p and a representative $\tilde{s}_p \in \mathcal{F}(U_p)$, that is $\tilde{s}_p = s_p$ in \mathcal{F}_p

Proposition 1.2.28

The set of compatible germs on $\prod_{p \in U} \mathcal{F}_p$ is precisely the image of $\mathcal{F}(U) \hookrightarrow \prod_{p \in U} \mathcal{F}_p$
